## Abstract

Ca. 100 words

*Keywords:* CAS, code-generation, Ruby

---

## 1. Motivation and significance

*Ruby*[1] is a purely object-oriented scripting language designed in the mid-1990s by Yukihiro Matsumoto (also known as *Matz*). It is internationally standardized since 2012 as ISO/IEC 30170.

With the advent of the *Internet of Things*, a written from scratch version of the *Ruby* interpreter called *mRuby* (*eMbedded Ruby*) [2] has been published on *GitHub* by Matsumoto in 2014. The new interpreter is a lightweight implementation aimed at both low power devices and personal computer that complies with the standard[3]. *mRuby* has a completely new API, and it is designed to be embedded in a complex project as a front-end interface — e.g. a numerical optimization suite may use *mRuby* to get problem input definitions.

The *Ruby* code-base exposes a a large set of utilities in core and standard library, that can be furthermore expanded through modules, also known as *gems*. Even the high number of gems deployed and available, there is no

---

*Email address:* `matteo.ragni@unitn.it` (Matteo Ragni)

16 library that implements a **automatic symbolic differentiation** (ASD) [4]  
17 engine that handles some basic computer algebra routines, compatible with  
18 all different *Ruby* interpreters flavours.

19 *Ruby* has matured its fame as a web oriented language with *Rails*, and  
20 can efficiently generate code in other languages. An ASD-capable gem is  
21 the fundamental step to rapidly develop a specific code generator for well  
22 known software — e.g. IPOPT [5].

23 The library described in this work, is a gem implemented in pure *Ruby* code  
24 — compatible with all standardized interpreters — that is able to perform  
25 symbolic differentiation (SD) and some computer algebra operations [6]. The  
26 library aims at:

- 27 • be an instrument for rapid development of prototype interface for nu-  
28 merical algorithms and exporting code generated in different target  
29 languages;
- 30 • generate rapidly descriptions of mathematical models, with *easy to im-*  
31 *plement* workaround for numerical issues, changing on request how the  
32 code is exported, and how expressions are formulated in the target lan-  
33 guage;
- 34 • *separate mathematical expressions from numerical workarounds*;
- 35 • create a complete open-source CAS system for the standard *Ruby* lan-  
36 guage, as a long-term ambitious impact.

37 This is not the first gem that tries to implement a CAS. The available  
38 computer algebra library for *Ruby* are:

39 *Rucas* [7], *Symbolic* [8] gems at early stage and with discontinued devel-  
40 oping status; they implement basic simplification routines. There is no

AD method, but it is one of the milestones. The development for both is currently discontinued.

**Symengine** [9] is a wrapper for the C++ library *symengine*. The backend library is very complete, but it is compatible only with the RVM *Ruby* interpreter. At the moment, the *SciRuby* project reports the gem as broken, and removed it from its codebase. From a direct test, when performing SD of an arbitrary function, the engine always returned `nil`.

## 2. Software description

### 2.1. Software Architecture

*ragini-cas* is an object oriented ASD gem that supports some computer algebra routines such as *simplifications* and *substitutions*. When gem is required, it automatically overloads methods of `Fixnum` and `Float` classes, to make them compatible with the fundamental symbolic class.

Each symbolic expression (or operation) is the instance of an object, that inherits from a common virtual ancestor: `CAS::Op`. An operation encapsulates sub-operations recursively, building a linked graph, that is the mathematical equivalent of function composition:

$$(f \circ g) \tag{1}$$

When a new operation is created, it is appended to the graph. The number of branches are determined by the parent container class of the current symbolic function. There are three possible containers. Single argument operations — e.g. `sin(·)` — have as closest parent the `CAS::Op` class, that links to one sub-graph. Expressions with two arguments — e.g. difference or exponential function — inherit from `CAS::BinaryOp`, that links to two subgraphs. Operations with arbitrary number of arguments — e.g. sum and product

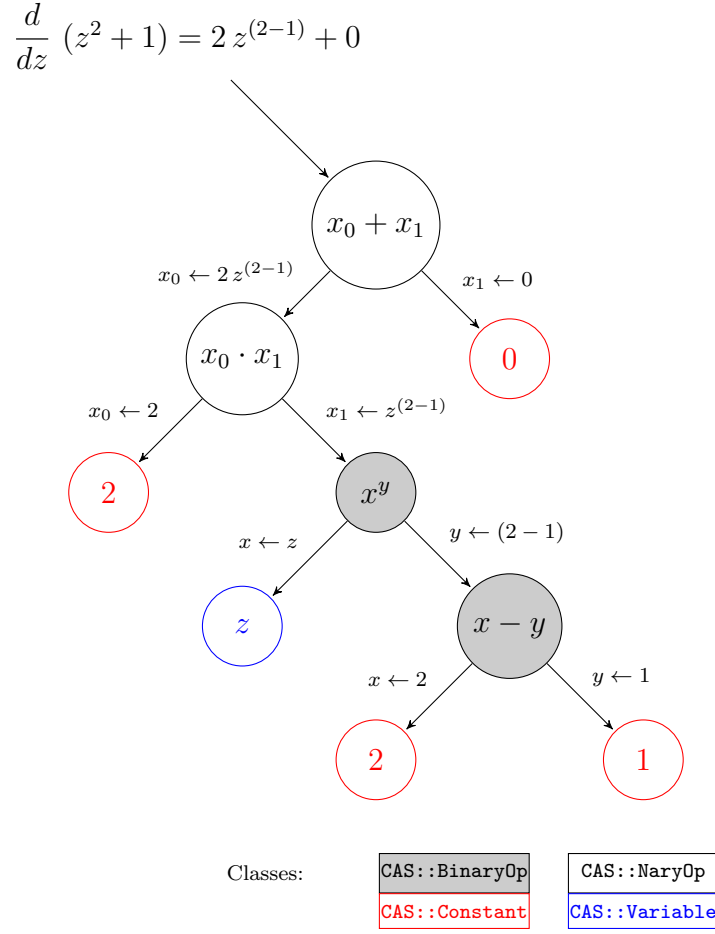

Figure 1: Example graph from the first function reported in listing 1

65 — have as parent the `CAS::NaryOp`<sup>1</sup>, that links to an arbitrary number of  
 66 subgraph. Figure 2.1 contains an example of graph. The different kind of  
 67 containers allows to introduce some properties — i.e. *associativity* and *com-*  
 68 *mutativity* for sums and multiplications [10]. Each container exposes the  
 69 subgraphs as instance properties. Containers interfaces and inheritances are  
 70 shown in Figure 2.1.

71 Terminal leafes of the graph are the classes `CAS::Constant`, `CAS::Varia-`

<sup>1</sup>Please note that this container is still at experimental stage

72 `ble` and `CAS::Function`. The first models a simple numerical value, while  
 73 the second represents an independent variable, that can be used to perform  
 74 derivatives and evaluations, and the latter is a prototype of an implicit func-  
 75 tion. As for now, those leafes exemplify only real scalar expressions, with  
 76 definition of complex, vectorial and matricial extensions as milestones for the  
 77 next major release.

78 `SD (CAS::Op#diff)` crosses the graph until it reaches the ending node.  
 79 The terminal node is the starting point for derivatives accumulation, the  
 80 mathematical equivalent of the chain rule:

$$(f \circ g)' = (f' \circ g) g' \quad (2)$$

81 The recursiveness is used also for simplifications (`CAS::Op#simplify`), sub-  
 82 stitutions (`CAS::Op#subs`), evaluations (`CAS::Op#call`) and code genera-  
 83 tion.

## 84 *2.2. Software Functionalities*

### 85 *2.2.1. Software installation and prerequisites*

86 Core functionalities has no dependencies. The gem can be installed  
 87 through *rbygems.org* provider: `gem install ragni-cas`. Functionalities  
 88 must be required runtime using the Kernel method: `require 'ragni-cas'`.  
 89 All methods and classes are encapsulated in the module `CAS`.

### 90 *2.2.2. Basic Functionalities*

91 `SD` can be performed with respect to an independent variable (`CAS::Va-`  
 92 `riable`) through forward accumulation, even for implicit functions. The dif-  
 93 ferentiation is done by a method of the `CAS::Op`, having a `CAS::Variable` as  
 94 argument:

Listing 1: Differentiation example

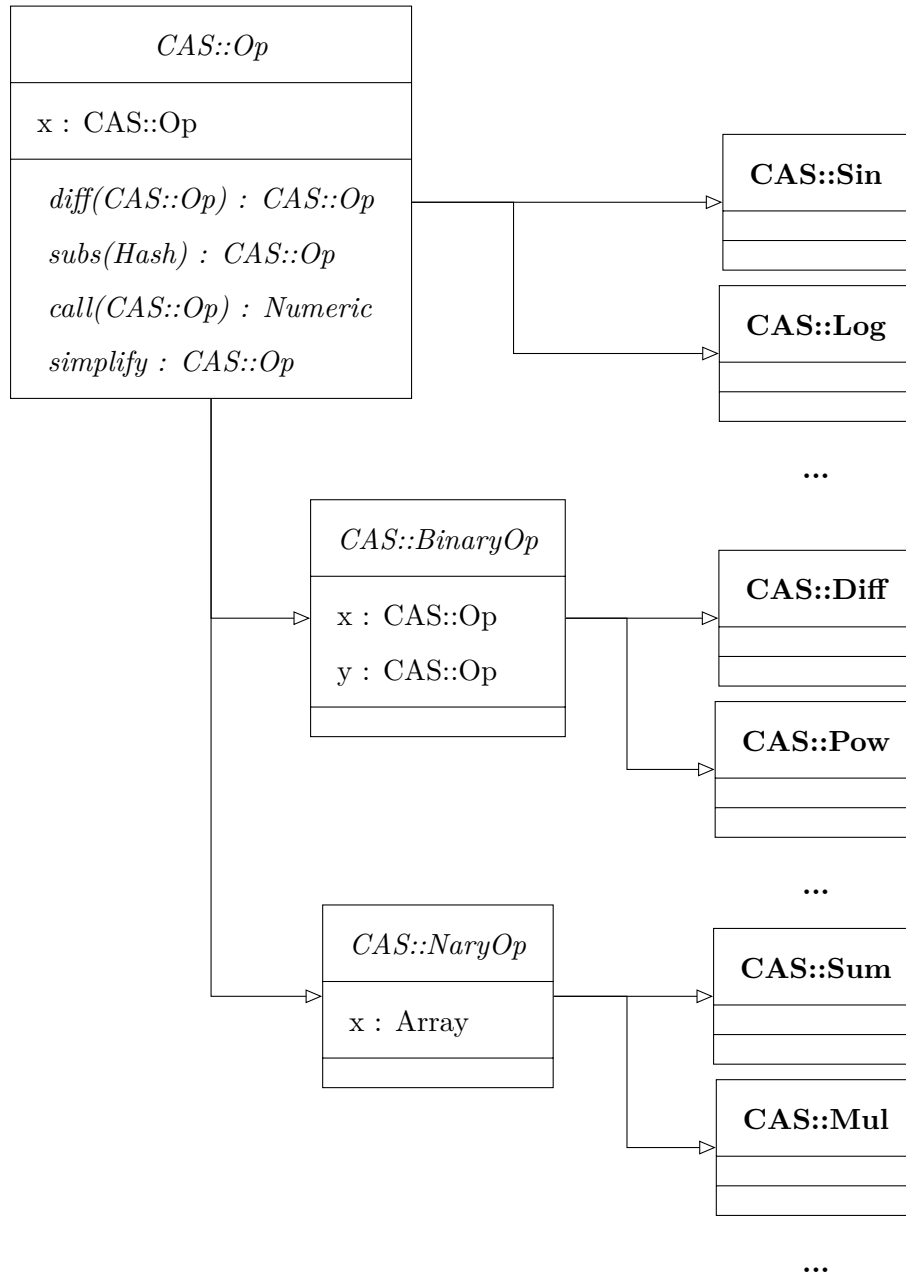

Figure 2: Simplified version of classes interface and inheritance

```

95
96 z = CAS.vars 'z'           # creates a variable
97 f = z ** 2 + 1            # define a symbolic expression
98 f.diff(z)                  # derivative w.r.t. z

```

```

99     # => 2 * z ^ (2 - 1) + 0
100    g = CAS.declare :g, f      # creates implicit expression
101    g.diff(z)                  # derivative w.r.t. z
102    # => (z ^ (2 - 1) * 2) * Dg[0](z ^ 2)
103

```

---

104     **Automatic differentiation** (AD) is implemented using dual numbers  
105 [11], and it is included as a plugin. This differentiation strategy can be used  
106 in case oectremely complex expressions, whose explicit derivative graph may  
107 exceed the call stack depth, that is platform dependent.

108     **Simplifications** are not executed automatically, after differentiations.  
109 Each node of the graph knows rules for simplify itself, and rules are called  
110 recursively inside the graph, exactly like ASD. Simplifications that require  
111 an *heuristic expansion* of the subgraph — i.e. some trigonometric identities  
112 — are not defined for now, but they can be easily achieved through **substi-**  
113 **tutions**:

Listing 2: Simplification example

```

114
115    x, y = CAS::vars 'x', 'y'      # creates two variables
116    f = CAS.log( CAS.sin( y ) )    # symbolic expression
117    f.subs y: CAS.asin(CAS.exp(x)) # perform substitution
118    f.simplify                      # simplify expression
119    # => x
120

```

---

121     The graph is numerically **evaluated** when independent variables values  
122 are provided in a feed dictionary. The graph is reduced recursively to a single  
123 numeric value:

Listing 3: Graph evaluation example

```

124
125    x = CAS.vars 'x'                # creates a variable
126    f = x ** 2 + 1                  # define a symbolic expression
127    f.call x => 2                    # evaluate for x = 2
128    # => 5
129

```

---

130     Symbolic expressions can be used to create comparative expressions —  
131 e.g.  $f(\cdot) \geq g(\cdot)$  — or piecewise functions — e.g.  $\max(f(\cdot), g(\cdot))$ :

Listing 4: Expressions and Piecewise functions

---

```

132
133 x, y = CAS.vars 'x', 'y'
134 f = CAS.declare :f, x
135 g = CAS.declare :g, x, y
136 f.greater_equal g
137 # => (f(x) >= g(x, y))
138 CAS::max f, g
139 # => ((f(x) >= g(x, y)) ? f(x) : g(x, y))
140

```

---

Comparative expression are stored in a special container classes, modeled by the ancestor `CAS::Condition`.

### 2.2.3. Metaprogramming and Code-Generation

The library is developed explicitly for **generation of code** for a target language, and **metaprogramming**. Expressions, once manipulated, can be exported as plain source code or used as a prototype for a callable *closure* (`Proc` object):

Listing 5: Graph evaluation example

---

```

148
149 x = CAS::vars 'x'           # creates a variable
150 f = CAS::log(CAS::sin(x))   # define a symbolic function
151
152 proc = f.as_proc           # exports callable lambda
153 proc.call 'x' => Math::PI/2
154 # => 0.0
155

```

---

Composing a closure of a graph is like making its snapshot, thus any further manipulation to the expression do not update the callable object. This drawback is balanced by the faster execution time of a `Proc`: when a graph needs only to be evaluated in a iterative algorithm, and not to be manipulated, transforming it in a *closure* reduces the execution time per iteration.

Code generation should be flexible enough to export a graph in a user's target language. Generation methods for common languages are included in specific plugins. Users can furthermore expand exporting capabilities by

164 writing specific exportation rules, overriding method for existing plugin, or  
 165 desining their own exporter:

Listing 6: Example of Ruby exportation plugin

---

```

166 # Definition
167 module CAS
168   {
169     # . . .
170     CAS::Variable => Proc.new { "#{name}" }
171     CAS::Sin      => Proc.new { "Math.sin(#{x.to_ruby})" },
172     # . . .
173   }.each do |cls, prc|
174     cls.send(:define_method, :to_ruby, &prc)
175   end
176 end
177
178 # Usage
179 x = CAS.vars 'x'
180 (CAS.sin(x)).to_ruby
181 # => Math.sin(x)
182
183 
```

---

### 184 3. Illustrative Examples

#### 185 3.1. Code Generation as C Library

186 This example shows how to export a C library using the **CAS** module as  
 187 design interface. **c-opt** plugin implements advanced features such as code  
 188 optimization and generation of libraries.

189 In this example we create a library **example** that implements the model:

$$f(x, y) = x^y + g(x) \log(\sin(x^y)) \quad (3)$$

190 Expression  $g(x)$  is implemented as **g\_impl** and its interface is described in  
 191 the external header **g\_impl.h**. The code must be optimized: the intermediate  
 192 operation  $x^y$  should be evaluated once, even if required twice in our model.  
 193 The C function that implements our model  $f(x, y)$  should be called with the

194 token `f_impl`. The exporter uses as default type, for variables and function  
 195 returned values, `double`.

Listing 7: Calling optimized-C exporter for library generation

```

196
197 require 'ragini-cas/c-opt'
198
199 # Models
200 x, y = CAS.vars :x, :y
201 g = CAS.declare :g, x
202
203 f = x ** y + g * CAS.log(CAS.sin(x ** y))
204
205 # Code Generation
206 g.c_name = 'g_impl'          # g token
207
208 CAS::CLib.create "example" do
209   include_local "g_impl"      # g header
210   implements_as "f_impl", f   # token for f
211 end
212

```

213 Library created by class `CLib` contains the following code:

Listing 8: C Header

```

// Header file for library: example.c

#ifndef example_H
#define example_H

// Standard Libraries
#include <math.h>

// Local Libraries
214 #include "g_impl"

// Definitions
#define M_PI 3.141592653589793
#define M_INFINITY HUGE_VAL
#define M_E 2.718281828459045
#define M_EPSILON 1.0e-16

// Functions
double f_impl(double x, double y);

#endif // example_H

```

Listing 9: C Source

```

// Source file for library: example.c

#include "example.h"

double f_impl(double x, double y) {
  double __t_0 = pow(x, y);
  double __t_1 = g_impl(x);
  double __t_2 = sin(__t_0);
  double __t_3 = log(__t_2);
  double __t_4 = (__t_1 + __t_3);
  double __t_5 = (__t_0 + __t_4);

  return __t_5;
}

// end of example.c

;

```

215 3.2. Using the module as interface

216 As example, an implementation of an algorithm that estimates the *order*  
 217 *of convergence* for trapezoidal integration scheme [12] is provided, using the  
 218 automatic differentiation as interface.

219 Given a function  $f(x)$ , the trapezoidal rule for primitive estimation in the  
 220 interval  $[a, b]$  is:

$$I_n(a, b) = \frac{b-a}{n} \left( \frac{f(a) + f(b)}{2} + \sum_{k=1}^{n-1} f\left(a + k \frac{b-a}{n}\right) \right) \quad (4)$$

221 where  $n$  mediates the integration's step size. When exact primitive  $F(x)$  is  
 222 known, approximation error is:

$$E[n] = F(b) - F(a) - I_n(a, b) \quad (5)$$

223 This error shows a direct relation:

$$E[n] \propto C n^{-p} \quad (6)$$

224 where  $p$  is the convergence order. Using a different value for  $n$ , for example  
 225  $2n$ :

$$\frac{E[n]}{E[2n]} \approx 2^p \quad \rightarrow \quad p \approx \log_2 \left( \frac{E[n]}{E[2n]} \right) \quad (7)$$

226 Following listings contain the implementation of the described procedure  
 227 using the described gem and the well known *Python* [13] library *sympy* [14].

Listing 10: Ruby version

```

require 'raggi-cas'

def integrate(f, a, b, n)
  h = (b - a) / n

  func = f.as_proc

  sum = ((func.call 'x' => a) +
        (func.call 'x' => b)) / 2.0

  for i in (1..n)
    sum += (func.call 'x' => (a + i*h))
  end
  return sum * h
end

228 def order(f, a, b, n)
  x = CAS.vars 'x'

  f_ab = (f.call x => b) -
        (f.call x => a)
  df = f.diff(x).simplify
  f_1n = integrate(df, a, b, n)
  f_2n = integrate(df, a, b, 2 * n)

  return Math.log(
    (f_ab - f_1n) /
    (f_ab - f_2n),
    2)
end

x = CAS.vars 'x'
f = CAS.arctan x

puts(order f, -1.0, 1.0, 100)
# => 1.9999999974244451

```

229

Listing 11: Python version

```

import sympy
import math

def integrate(f, a, b, n):
  h = (b - a)/n
  x = sympy.symbols('x')
  func = sympy.lambdify((x), f)

  sums = (func(a) +
        func(b)) / 2.0

  for i in range(1, n):
    sums += func(a + i*h)

  return sums * h

def order(f, a, b, n):
  x = sympy.symbols('x')

  f_ab = sympy.Subs(f, (x), (b)).n() - \
        sympy.Subs(f, (x), (a)).n()
  df = f.diff(x)
  f_1n = integrate(df, a, b, n)
  f_2n = integrate(df, a, b, 2 * n)

  return math.log(
    (f_ab - f_1n) /
    (f_ab - f_2n),
    2)

x = sympy.symbols('x')
f = sympy.atan(x)

print(order(f, -1.0, 1.0, 100))
# => 1.9999999974244451

```
